HERO Compliant Electric Primer for Tank Ammunition

Presented by: Jason Mishock

8 April 2009
Background for the Need for a HERO Safe Primer

- **Definition:**

  **HERO (Hazards of Electromagnetic Radiation to Ordnance)**

- Primer testing was conducted to ensure that the radios used on the M1A1/A2 SEP Abrams tank platforms were compatible with the 120mm main gun ammunition.

- Test results showed that the current primer did not have an issue with the current tank configuration but still did not meet the HERO requirements.

- Ammunition currently does not meet the MIL-STD-464A for HERO compliance. This restricts the handling of the ammunition while outside its packaging container when in certain RF (Radio Frequency) conditions. One example is during shipment on Naval ships.
Basic Electromagnetic Theory

Maximum human body absorption of RF energy is from 40MHZ - 90MHz

$\text{Battery}$

$I_{\text{all-fire}}$

$R_M$

$P \times A$

$I_{\text{all-fire}}$

$R_D = \text{Attenuation factor due to distance.}$

$R_C = \text{Attenuation factor due to coupling.}$
Problem Statement

- Current P/N 12525143 thick wall primer’s ignition element is **not** HERO compliant
- Current primer has several features that can lead to critical defects in manufacturing
- Current primer is very labor intensive to build
- Purple lacquer for sealing the flash hole may not be available in the near future
The M125 Thickwall Primer has many critical characteristics and is difficult to manufacture.
The improved Thickwall Primer eliminates most critical characteristics and is easier to manufacture.
HERO Safe Primer

Simple
- Fewer parts
- Reduced labor
- Lower cost for ignition element
- Less to go wrong in manufacturing
HERO Safe Primer

Compatible

- One igniter design for all tank ammunition primers

  Primer, Electric (current development)
  M129 (future development)
  M123A1 (future development)
System Requirements

- Must meet HERO requirement per MIL-STD 464A
- Must meet ESD requirements per MIL-STD 331C, subtest F1
- Must meet 120mm International Control Document (ICD) requirements
- Must meet fire control on M1A1/A2 Abrams tanks
  - Must be compatible with Blasting machine
- No degradation in ballistic performance
- Minimize cost increase over the current design
Primer Ignition Train Redesign Concepts

Glass to metal header
- Electrode is molded with a glass insulator that is pressed into igniter element base with a welded bridge wire making a more robust design
- Ignition mix is environmentally friendly – ZPC (Zirconium Potassium Chlorate)
- Meets initial HERO requirements
- Meets initial ESD requirements
- Meets system requirements for both US and international standards (ICD)
- Met cost requirements – currently will be less costly than current design
  – Note: One piece body design for the M125 primer will increase cost

Current ballistic requirements
- Cold condition is up to 5 ms slower than controls
Current Primer vs. Redesign Primer

Current primer data
- No fire 210 mA
- All fire 1.25 Amps
- Paper and lacquer seal for primer tube
- Three piece body design

Initial primer redesign data
- No fire 1.12 amps
- All fire 2.18 amps
- Plastic liner seal for primer tube
- One piece body design

Future Schedule
- Phase 1-3 (completed)
- Phase 4 – Finalize design and verification testing – estimated completion date – August 2009
- Qualification testing – estimated completion date – 31 December 2009
